Introduction

Since the COVID-19 pandemic spread in early 2020, extensive research has been performed on the impact of various social, political, and economic variables on how well people across the world have followed government officials mandates and executive orders. This issue is of great importance because for a respiratory virus like COVID-19, simple and easy remedies such as mask usage and stay at home orders can significantly lower the spread so the healthcare system would not be overwhelmed with new patients, and a lower rate of infection would be observed. ¹

What is generally believed is that all governmental and international organizational orders in times of pandemic will be treated the same by the populations and if people respond positively to one mandate, they will without a doubt respond the same way to the others as well.

For example, it is a common belief that during the COVID-19 pandemic, people who did not follow healthcare official's mask mandate because of various socio-political reasons did not also follow shelter in place orders and ended up not participating in vaccination procedures once it became available.

This belief is in fact not true and we show that impact of each socioeconomic variable on population's willingness to cooperate with healthcare officials when expected to follow a mandate or to participate in vaccination depends on a variety of factors such

¹ https://www.sciencedirect.com/science/article/pii/S2468042720300117

as politician's behavior, level of education, proximity to densely populated cities, etc. In short, we show that people responded differently to different mandates by healthcare officials and U.S. government orders and the reason behind this discrepancy is further analyzed in this work.

Discussion

When looking at various socioeconomic variables and attempting to isolate their impact on Mask Adoption, Movement Change, and Vaccination Participation, several key facts need to be considered:

Mask Mandate Adoption is not necessarily highly correlated with other governmental orders such as Shelter in Place orders which is captured under Movement Change in this work. We show that using %Essential Workers Population in each county. These are people who may want to comply with any and all governmental mandates but because they have to be mobile, will not be able to stay at home, but that does not necessarily mean they do not follow other governmental orders.

As can be seen in the regression tables, Essential Workers in each country did not comply with the Mask Mandate and also moved significantly more compared to other people but took up the vaccination at a good rate.

Another example of this can be counties where Trump had the highest share of votes in the 2020 elections, 4 months after the collection of movement and mask adoption data used in this research. As it can be seen, in those counties, there is a lower Always mask adoption and more change in movement, however, unlike what would be expected, there is no correlation between voting for Trump and Vaccination Participation.

This can be explained by the behaviour of politicians and how impactful their behaviours can be on the population. Since the Trump administration was the government in charge when the vaccine was developed and released, the vaccination participation, or in other words following governmental orders, has been shown to be far more compliant than mask use adoption and stay at home orders.

Another important factor to consider when comparing population's response to governmental orders in time of pandemic is considering how dense the population is and how rural that county might be based on the most recent measurements to come to an accurate conclusion.

As can be seen in the US map comparisons between %Rurality and Mask Use Adoption, there is a positive correlation between a county being rural and complying less with the mask mandate. One possible explanation might be that since the population of people is less dense in the rural areas, people might not see the need to 'Always' follow the mask mandate but if they would be in a more populated city, they will put on a mask at all times.

There also seems like a strong correlation between %population with at least a college degree or higher and vaccination participation. This can be a good policy recommendation which can suggest to governments to invest more on educating the population so in times of pandemics they would be more compliant with beneficial remedies such as vaccination.

Finally, it is important to point out that performing sufficient testing seems to have a strong correlation with more mask wearing, less change in movement, and more vaccination participation. Same relationship can be seen in the announcement of confirmed COVID cases or COVID death cases which suggests that being transparent and educating the public and at the same time providing enough testing to them significantly improves governmental order adoption by the population.

Conclusion

| Observed in the Data | Policy Recommendation |
|--|---|
| No correlation between voting for Trump and Vaccination Participation in Counties voting for Trump | Politician's behaviour matters and impacts people's response to remedies to pandemics |
| Strong correlation between Education (College Degree or Above) and Vaccination Participation | Governments should invest more on high education as it seems like it has externalities in healthcare as well |
| Difference in Essential Workers response to different governmental orders | Governments need to take into account segmentation of people in each county when analyzing population's response to orders |
| Availability of Testing and Clinics in each county and transparency in confirmed or deceased cases from COVID has strong correlations with being compliant | Governments should provide ample testing and plan on being transparent with people about the COVID statistics since it leads to population's cooperation. |
| Strong correlation between not complying with Mask Mandate and %Rurality in counties | In addition to considering people's socioeconomic status when analyzing population's response to governmental orders, governments should investigate other county specific variables such as %Rurality and Population Density to better understand people's behaviour in times of pandemic and in response to orders. |
